Abstract

Software security has become increasingly important since hacking and other attacks on computer systems have grown in popularity in the last few years. As a result, several researchers have examined security solutions as early as the requirement engineering phase. With the growth of the software business and the internet, there is a need to understand the security risks against each phase of the software development life cycle (SDLC). This study aims to empirically investigate and prioritize the risks that could negatively impact the software security aspects of SDLC in the context of global software development (GSD). To achieve the study objectives, we conducted an industrial empirical study to determine the impact of software security threats against each phase of SDLC. Furthermore, the fuzzy analytical hierarchy process (FAHP) was used to prioritize the list of software security risks against the SDLC. The results and analysis of this study provide a ranked-based decision-making framework, which assists the practitioners in considering the most critical security risks on priority. The results show, "improper plan for secure requirement identification, inception, authentication, authorization, and privacy", "lack of threat models updating", "lack of output validation", "lack of certification in the final release and archive", and "spoofing" are declared as top ranked security risks of SDLC in GSD. In addition, the application of FAHP is novel in this domain as it is helpful to address multicriteria decisionmaking problems.

Keywords: Software Security, Security Risks, Software Development Life Cycle (SDLC), Secure Software Engineering, Fuzzy Analytical Hierarchy Process (FAHP)

1. Introduction

One of the most critical issues facing companies is implementing and managing security in the software development lifecycle (SDLC) [1, 2]. A set of software security standards, guidelines, practices, and certifications can be used to assist in the creation of secure software applications [3]. However, despite the widespread understanding of the importance of presenting scenarios covering the entire SDLC of secure software development, only a few have been documented [4]. Understanding Secure Software Engineering (SSE) methodologies are becoming increasingly important in tackling the problem's technological and psychological components [2]. Secure software engineering (SSE) is the process of designing, building, and testing software so that it becomes secure; this includes secure SDLC processes and secure software development (SSD) methods [5-7]. To produce secure software, one must adhere to the following four steps: software requirements security requirements, implement threat modeling approaches during software design, and adhere to best security practices when coding, reviewing code, and performing testing [6]. This process must be constantly updated to ensure that software products are secure; thus, research indicating the trends in methods, notations, tools, and techniques is needed [1].

1.1 Rational for the Review in the Context of Existing Knowledge

Contrarily, misusing software can lead to significant financial losses, sabotage in the communications industry, data theft in databases, and even human life-threatening software abuse in missile control systems [9, 10]. Khan [11] stated that security concerns heavily influence software quality as software development grows more complicated, distributed, and concurrent. Insecure software affects an organization's reputation with customers, partners, and investors; it raises expenses, as enterprises are obliged to patch unreliable programs; and it delays other development efforts as scarce resources are assigned to address present software problems [11]. The lack of prioritizing security is one of the major causes of widespread vulnerabilities [8]. Even the most conscientious organizations use the "fix and penetrate" strategy in which security is accessed after a project is completed [8]. The disadvantage is that the users do not apply the patches themselves. Aside from that, attackers may devise strategies to exploit new security flaws [12]. Much money was invested in traditional security methods, mainly focused on network systems. They primarily include IDS (Intrusion Detection System), firewalls, encryption, antivirus, and antispyware protection [5, 13].

Although identifying software security threats and implementing secure SDLC techniques is critical, little work has been done on creating secure software development tools, models, and standards [4, 14]. Our previous published study explored the software security risks and their practices in the SDLC phases [2].

1.2 Research Goals and Questions

The following goals are being pursued in the current study: (1) We conduct a questionnaire survey to gather information from global software development experts (researchers and practitioners alike) on the security risks in the SDLC phases. (2) Using the fuzzy analytical hierarchy process (FAHP), rank the investigated security risks regarding their importance to secure SDLC phases in the context of GSD.

However, no research has prioritized the security risks of SDLC phases in the context of global software development. To address software security issues in the context of GSD, we applied the FAHP technique. We believe that a thorough awareness of software security threats throughout the SDLC phases will aid GSD organizations in implementing required secure software development modifications effectively and efficiently. The ranking of security risks helps GSD organizations prioritize the most critical security concerns necessary for successfully implementing software security activities in the context of GSD. This study's goals are met through the following research questions:

RQ1: What are the most cited software security risks in the SDLC phases in the domain of GSD? **RQ2:** What is the best way to prioritize the significant software security risks that have been identified? **RQ3:** What would be the decision-making framework for the critical software security risks?

The rest of the paper reads as follows: Section 2 provides an overview of the research. Section 3 goes into detail about the study's methodology. The results of the study can be found in Section 4. Results evaluation and analysis are provided in Section 5. Section 6 investigates the study's limitations. Section 7 provides the Implications of the Study. Section 8 provides a conclusion and directions for future research.

2. Background and Motivation

Software security is the concept of creating software that continues to function even when it is attacked maliciously [10, 15]. The best strategy to eliminate software bugs/vulnerabilities is to incorporate security and non-functional specifications into all phases of the SDLC [2, 16]. There has been considerable research on "high integrity" throughout the years, and scholars and practitioners have worked diligently to

produce secure software systems. This section addresses the various approaches to integrating security into the SDLC phases, as well as the security techniques that are frequently utilized in these approaches:

- CMMI, Microsoft Software Development Life Cycle (MS-SDL), Misuse case modeling, Abuse case modeling, Knowledge Acquisition for Automated Specification, System Security Engineering-Capability Maturity Model (SSE-CMM), OWASP, and Secure Tropos Methodology[16].
- McGraw [17, 18] recommends seven touchpoint operations (Abuse cases, Security requirements, Architectural risk analysis, code review and repair, Penetration testing, and security operations) for creating secure software, all of which are connected to software development artifacts.
- Sodiya [19] developed the Secure Software Development Model (SSDM), which provides training to stakeholders in software development with adequate security education.
- Al-Matouq et al. [12] designed a framework Secure Software Design Maturity Model (SSDMM), and the results show that SSDMM helps measure the maturity level of software development organizations.
- Flechas et al. [20] developed AEGIS (Appropriate and Effective Guidance for Information Security), first evaluating device assets and their relationships, then moving on to risk analysis, which defines weaknesses, threats, and risks.
- Gupta et al. [21] developed Team Software Process for Secure Software Development (TSP) specifically for software teams to help them create a high-performance team and prepare their work to produce the best results.
- The Software Engineering Institute (SEI) at Carnegie Mellon University developed the Capability Maturity Model Integration (CMMI) [22] process model, which assists companies measure and improving their development processes while also delivering high-quality products.
- Al-Qutaish and Abran [23] proposed the Software Product Quality Maturity Model (SPQMM), which measures the quality of a software product.
- B. Golden, [24] introduced the Open Source Maturity Model (OSMM) to assess open-source products.
- April et al. [25] proposed the Software Maintenance Maturity Model (SMmm), based on the CMMI, to assess and improve the quality of software maintenance activities.
- Turetken et al. [26] developed a maturity model to assess the Scaled Agile Framework (SAFe), which integrates agile software development practices in traditional large-scale projects.
- Da Silva and de Barros [27] presented an information security maturity model for software developers based on ISO 27001; it was evaluated by subject experts and utilized to measure the maturity level of several organizations.
- S. R. Ahmed [28] identified security activities that should be performed to build secure software and has shown how the security activities are related to usual activities in different phases of software development.
- Essafi et al. [29] developed the Secure Software Development Process Model (S2D-ProM), a strategy-oriented process model that offers guidance and support to developers and software engineers at all levels, from beginners to experts to build secure software.
- Niazi et al. [8] conducted a systematic literature review (SLR) to pinpoint the required practices for developing secure software and identifying best requirement practices. A framework for secure requirement engineering named Requirements Engineering Security Maturity Model (RESMM) was developed.
- Manico [30] designed the Comprehensive, Lightweight Application Security Process (CLASP), which consists of 24 high-level security activities that can be entirely or partially integrated into software during the SDLC.
- The Open Web Application Security Project (OWASP) created the Software Assurance Maturity Paradigm (SAMM) [30], which is a non-commercial model and is an open platform that aids software companies in developing and implementing software security policies.

- The Building Security In Maturity Model (BSIMM) [31] quantifies numerous businesses' security activities and provides a common foundation for them to compare their security endeavours to those of others. There are 119 activities in the BSIMM 10 software security framework. These activities are divided into twelve practices. Each practice's exercises are divided into three maturity levels.
- Security Quality Requirements Engineering (SQUARE) methodology allows for elicitation, classification, and prioritization of security specifications for information technology systems and applications [32].

We conclude from the above discussion that none of these models or structures is explicitly committed to recognizing security risks/threats in the SDLC context of GSD. Furthermore, no study identified and prioritized software security issues during the SDLC phases. An empirical study that analyses security threats and ranks them according to their importance for secure SDLC in GSD is required to fill this research gap.

The study results give a taxonomy that will assist the GSD organizations in developing secure software by developing new and effective strategies to handle the security aspects of SDLC. Apart from that, the knowledge gained from identifying security risks will aid in developing a generic model that would be useful to GSD organizations in effectively implementing security checks against each phase of SDLC. To address the objective of this study, we collected the industry practitioners' insights using a questionnaire survey approach.

Additionally, we apply an expert opinion approach to quantify the discovered security risks against each phase of SDLC. The discovered security risks and their categories were prioritized by calculating the relative weight of each important security risk and its categories. As a result, determining the significance and priority of numerous security risks and categories may be referred to as the multi-criterion decision-making (MCDM) dilemma [33-36]. Numerous decision-making techniques exist [37-42]. Thus, we applied the fuzzy AHP technique as it is an effective way to handle the MCDM. Considering the successfulness of fuzzy AHP in other engineering domains, we also consider it to prioritize the identified security risks against each phase of SDLC.

3. Research Methodology

To achieve the objective of this study, the research work is designed in three steps. A brief description of all the steps is given in subsequent sections:

3.1 Step-1: Identifying software security risks of SDLC in the context of global software development

To explore the software security risks of SDLC in the context of global software development, we used a systematic literature review (SLR) method, and the preliminary findings were published in prior work [2]. An SLR is a secondary study in which primary studies are examined impartially and iteratively to define, interpret, and discuss evidence relevant to the research questions [43-46]. The step-by-step directions of Kitchenham and Charters [44] were followed to conduct the SLR. According to Kitchenham[47], SLR findings are more valid and exhaustive since they are conducted according to predefined protocols. To investigate software security risks during the SDLC phases, Khan et al. [2] thoroughly follow all the SLR processes, namely planning the review, conducting the review, and reporting the review.

One hundred twenty-one papers were selected via the tollgate technique [48] based on the inclusion, exclusion, and quality rating criteria. Khan et al. [2] identified 145 security risks and 424 best practices that help software development organizations to manage security throughout the SDLC phases. Afzal et al. [48] suggested the tollgate method was used to refine the research articles found during the primary study collection.

3.2 Step-2: Empirical Investigation

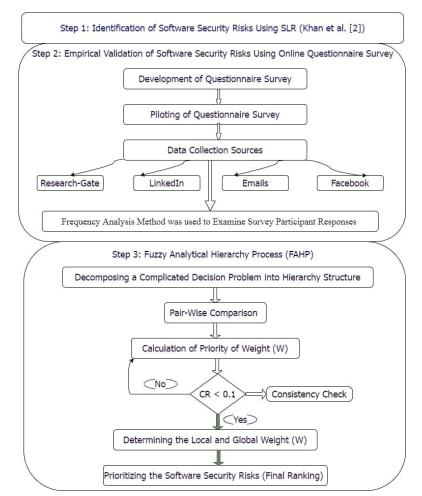

Figure 1: Flowchart of Research Methodology

A key goal of empirical research in software engineering is to assess practical significance, which answers whether the observed effects of some compared treatments show a relevant difference in practice in realistic scenarios. Even though plenty of standard techniques exist to assess statistical significance, connecting it to practical significance is not straightforward or routinely done; only a few empirical studies in software engineering assess practical importance conscientiously and systematically [49].

Many empirical research articles have been published recently [49-53] to address the software security issues. To address this objective, an online questionnaire survey was constructed using Google Docs to validate the SLR findings and discover other security risks and associated practices.

It is difficult to obtain data directly from large numbers of industry experts working across the globe. As a result, we used a non-methodical technique for data collecting, namely an online survey using snow balling technique. Other researchers in the software engineering domain also employed the same

date collection process [54-60]. The following steps were involved in conducting the questionnaire survey:

3.2.1 Development of Questionnaire Survey

The questionnaire primarily consists of closed-ended questions designed to get the practitioner's insight concerning the security risks of SDLC in the GSD context. The questionnaire also contains an open-ended section to allow the survey participant to add any additional security risk of SDLC in GSD. We employed a five-point Likert (strongly-agree to strongly-disagree)scale to obtain survey participants' observations regarding the software security risks and practices listed in the closed-ended section, i.e., strongly agree, agree, neutral, disagree, and strongly disagree.

3.2.2 Pilot of Questionnaire Survey

To conduct the pilot assessment of the questionnaire survey, we chose experts working in the GSD environment (i.e., Software Engineering Research Group (SERG UOM) Pakistan, King Fahd University of Petroleum and Minerals, Saudi Arabia, and Qatar University, Doha, Qatar). This pilot assessment aims to address significant issues (in terms of statistical variables) and improve the survey questions' understandability. Experts suggest improving the questionnaire's design by adding questions to obtain more information about survey participants. The questionnaire survey was revised after considering the experts' ideas and recommendations.

At the beginning of the survey, a statement on the researchers' ethical responsibility was also added to assure the participant's confidentiality. This remark reassured the participants that only the study team would access their information. It was stated that the research team would not share the data with anyone to reveal the identity of any participant or organization.

3.2.2 Data Collection Sources

As previously indicated, our target population was large and spread organizations across the globe. We decided to use unusual methods to collect responses from SSD professionals working in GSD. We used the snowball sampling technique to gather data from the experts [61]. Snowballing is a low-cost, straightforward strategy to reach a specific audience [57, 61, 62].

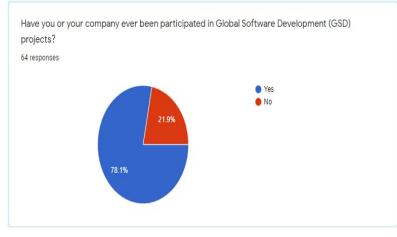

FIGURE 2. Respondents Responses

We used social media networks such as Facebook, LinkedIn, Research Gate, and email to contact the experts. The empirical study's data was collected online from June 01, 2021, to July 04, 2021, and the entire data gathering process took one month and four days. During the survey's implementation, 64 responses were collected, as shown in Figure 2. All of the responses were manually reviewed. We excluded 14 responses because the respondents of these 14 persons do not have experience in GSD and software security. For analysis, the final 50 survey results were taken into account. We ensure survey participants that the obtained data will only be used for research purposes and that their identities will never be disclosed to a third party. Appendix A lists all of the countries and their responses.

3.2.4 Data Analysis

The frequency analysis method was used to examine survey participant replies in this study. This approach analyzes nominal and ordinal data over many variables or groups of variables [63]. Because the survey responses are nominal, we employed the chi-square ("liner-by-linear connection") technique to discover significant differences across the variables. Research with similar data types has used the same analysis approach [62, 64].

3.4 Step-3: Fuzzy Analytical Hierarchy Process (FAHP) Survey

The respondents to the first survey were contacted and asked to participate in a second survey that used the FAHP technique to rank software security risks and their categories. We obtained 27 complete responses from respondents in the second survey. Appendix A contains an example of the questionnaire used to collect data for the second survey. Compared to the previous survey, the FAHP survey had a smaller sample size (27 replies), threatening the generalizability of our results. The FAHP method, on the other hand, has been viewed as a more subjective approach that allows for smaller sample size [65-68].

3.4.1 Fuzzy Set Theory and AHP

This section discusses the basics of fuzzy set theory and how to use it in the traditional AHP method. Several MCDM approaches include AHP, Fuzzy AHP, Fuzzy TOPSIS, etc. AHP is the most popular because it is very effective [33, 69, 70]. Various areas, including political, economic, and management sciences, have extensively used AHP to solve complicated problems. When measuring multiple criteria's relative importance, classical AHP cannot handle the ambiguity and obscurity of the decision-maker. Because of this, fuzzy AHP was developed, which outperformed AHP in terms of accuracy and efficiency [71-73]. With these insights in mind, we chose fuzzy AHP over other approaches.

3.4.2 Fuzzy Set Theory

Zadeh [74] developed a fuzzy set theory to extend the traditional set theory. It was designed to manage ambiguous responses in decision-making tasks based on numerous criteria to deal with uncertainties and ambiguity in real-world situations. The fuzzy set theory is a valuable tool [75, 76]. A characteristic function $\mu_V(x)$ is inserted into the fuzzy set, which maps a given value's membership between 0 and 1. The following sections describe the fundamental principles and definitions of fuzzy sets:

Definition: Triangular fuzzy number (TFN) Vis represented by a triplet (v^l, v^m, v^u) . The characteristic function $\mu_V(x)$ of a TFN is given in equation (1) and Figure 3.

$$\mu_{v}(x) = \begin{cases} \frac{x - v^{l}}{v^{m} - v^{l}}, & v^{l} \leq x \leq v^{m} \\ \frac{v^{u} - x}{v^{u} - v^{m}}, & v^{m} \leq x \leq v^{u} \\ 0, & O \ th \ er \ w \ is \ e \end{cases}$$
(1)

Where v^l represents the lowest, v^m represents the most favourable, and v^u denotes the highest possible values.

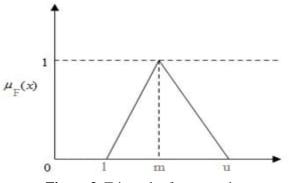

Figure 3. Triangular fuzzy number

Table 1 lists the most typically used algebraic procedures between two TFNs (V_1 , V_2).

Operation Law	Expression
Addition $(V_1 \oplus V_2)$	$(v^{l}_{1,}v^{m}_{1,}v^{u}_{1})_{\oplus}(v^{l}_{2,}v^{m}_{2,}v^{u}_{2}) = (v^{l}_{1} + v^{l}_{2,}v^{m}_{1} + v^{m}_{2,}v^{u}_{1} + v^{u}_{2})$
Subtraction $(V_1 \oplus V_2)$	$(v_{1,}^{l}v_{1,}^{m}v_{1,}^{u}v_{1}^{u})_{\oplus}(v_{2,}^{l}v_{2,}^{m}v_{2,}^{u}) = (v_{1}^{l} - v_{2,}^{l}v_{1}^{m} - v_{2,}^{m}v_{1}^{u} - v_{2,}^{u}v_{1}^{u} - v_{2,}^{u}v_{2,}^{u})$
Multiplication $(V_1 \oplus V_2))$	$(v^{l}_{1,}v^{m}_{1,}v^{u}_{1})_{\oplus}(v^{l}_{2,}v^{m}_{2,}v^{u}_{2}) = (v^{l}_{1}*v^{l}_{2,}v^{m}_{1}*v^{m}_{2,}v^{u}_{1}*v^{u}_{2})$
Division $(V_1 \oplus V_2)$	$((v_{1,1}^{l}v_{1,1}^{m}v_{1,1}^{u})_{\bigoplus}(v_{2,1}^{l}v_{2,1}^{m}v_{2,1}^{u}) = (v_{1/1}^{l}/v_{2,1}^{l}v_{1/1}^{m}v_{2,1}^{m}v_{1/1}^{u}v_{2,1}^{u})$
Inverse $(V_1 \oplus V_2)$	$(v^{l}_{1,}v^{m}_{1,}v^{u}_{1})^{-1} = (\ 1/\ v^{l}_{1}\ ,\ 1/\ v^{m}_{1}\ ,\ 1/\ v^{u}_{1})$
For any real number $k (kV_1)$	$k(v_{1,}^{l}v_{1,}^{m}v_{1,}^{u}v_{1}) = (k \ v_{1,}^{l}k \ v_{1,}^{m}kv_{1,}^{u}v_{1})$

 Table 1. Triangular fuzzy numbers

3.4.3 Fuzzy analytical hierarchy process (FAHP)

Practitioners widely accept that the FAHP is useful for dealing with complex decision-making situations. The most critical aspect of FAHP is its ability to efficiently deal with qualitative and quantitative data that contain many criteria. The significant steps for performing FAHP analysis are as follows:

Step 1: The decision problem is broken down into a hierarchical structure. (See Figure 3)

Step 2: The priority vector is calculated by pair-wise comparison for each level of the hierarchy.

Step 3: Calculate the pair-wise consistency ratio.

Step 4: Prioritize each component and sub-factor based on their weight in the overall score. (See Figure 4).

Even though different FAHP approaches are accessible in the literature [65-68], we have used Chang's method [77] because of its effectiveness and widespread acceptance among scientists. Chang [77] expressed a prioritisation problem as a group of elements referred to as primary categories as $X = \{x_1, x_2,...,x_m\}$. Each x_i also contains elements, called goal set, and represented as $V = \{v_1, v_2,...,v_n\}$. At a time, one main category, x_i , is considered, and each goal g_i undergoes extent analysis. The following equations(2) and(3) can be used to calculate the number of extent analyses (m) that are performed for each category:

$$V_{gi}^{1}, V_{gi}^{2}, ..., V_{gi}^{m}, \qquad (2)$$

$$i = 1, 2, ..., n \qquad (3)$$

Where, all V_{gi}^{j} (j = 1, 2, ..., m) are TFNs. Chang's step-by-step extent analysis method is described as follows [77]:

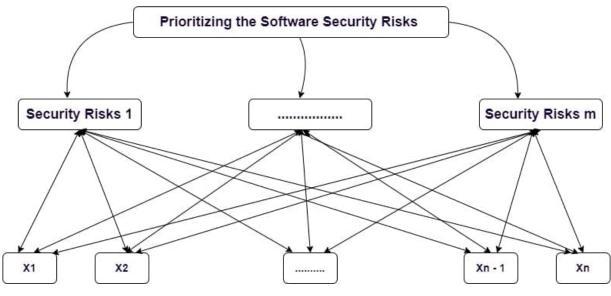

Figure 4. FAHP decision hierarchy

Step 1:The fuzzy analysis of the ith category is shown in Equation (4) as:

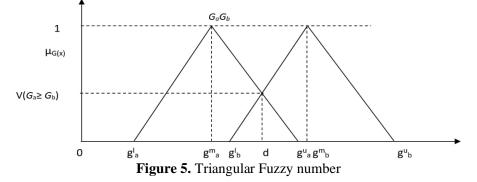

$$L_{i} = \sum_{j=1}^{m} V_{gi}^{j} \otimes \left[\sum_{i=1}^{n} \sum_{j=1}^{m} V_{gi}^{j}\right]^{-1}$$
(4)
Where $\sum_{j=1}^{m} V_{gi}^{j}$ can be calculated as :
$$\sum_{j=1}^{m} V_{gi}^{j} = \left(\sum_{i=1}^{m} v_{gi}^{i}, \sum_{i=1}^{m} v_{gi}^{m}, \sum_{i=1}^{m} v_{gi}^{u}\right)$$
(5)
and $\left[\sum_{i=1}^{n} \sum_{j=1}^{m} V_{gi}^{j}\right]^{-1}$ can be calculated, as mentioned in equation (6) and (7):
 $\sum_{i=1}^{n} \sum_{j=1}^{m} V_{gi}^{j} = \left(\sum_{i=1}^{n} v_{i}^{i}, \sum_{i=1}^{n} v_{i}^{m}, \sum_{i=1}^{n} v_{i}^{u}\right)$ (6)
 $\left[\sum_{i=1}^{n} \sum_{j=1}^{m} V_{gi}^{j}\right]^{-1} = \left(\frac{1}{\sum_{i=1}^{n} v_{i}^{u}}, \frac{1}{\sum_{i=1}^{n} v_{i}^{m}}, \frac{1}{\sum_{i=1}^{n} v_{i}^{i}}\right)$ (7)

Step 2: Given two TFNs V_a and V_b, the degree of possibility that $V_a \ge V_b$ can be defined as:

$$V(V_{a} \ge V_{b}) = \sup[\min(\mu_{V_{a}}(x), (\mu_{V_{b}}(x))]$$
(8)
Or more specifically as:

$$V(V_{a} \ge V_{b}) = hgt(V_{a} \cap V_{b}) = \mu_{V_{a}}(d) = \begin{cases} 1 & \text{if } v^{m}_{a} \ge v^{m}_{b} \\ \frac{v^{u}_{a} - v^{l}_{b}}{(v^{u}_{a} - v^{m}_{a}) + (v^{m}_{b} - v^{l}_{b})} & v^{l}_{b} \le v^{u}_{a} \\ 0 & Otherwise \end{cases}$$
(9)

Where d indicates the largest value of intersection between μ_{Ga} and μ_{Vb} (Figure 5)

Step 3: The overall degree of possibility of a given convex fuzzy number H is calculated concerning other V_i (*i*= 1, 2,..., *k*) as:

$$H(V \ge V_1, V_2, V_3, \dots, V_k) = \min H(V \ge V_i)$$
(10)

Assuming that,

$$d'(V_i) = \min H (V_i \ge V_k) \tag{11}$$

Where $\mathbf{k} = 1, 2, \dots, n$ and $k \neq i$.

The weight vector can be calculated using Eq. 11 as:

$$W' = (d'(V_1), d'(V_2), d'(V_3), \dots, d'(V_n))$$
(12)

Where, V_i (i=1,2,...,n) are *n* separate fuzzy numbers.

Step 4: The weight vector W obtained from equation (12) is normalized to achieve priority weight as a crisp number:

$$W = (d(V_1), d(V_2), d(V_3), \dots, d(V_n))$$
(13)

here, W represents a crisp number.

Step 5: Checking consistency ratio: FAHP requires that the pair-wise matrices be consistent at all times [39]. Thus, a consistency ratio is calculated for each pair of comparison matrices, referred to as a consistency check. A graded mean integration approach converts the given matrix with a fuzzy number into corresponding crisp values. This is referred to as defuzzification. To convert a given TFN P = (1, m, u) into an equivalent crisp number, the following formula must be utilized:

$$P_{crisp} = \frac{(4m+l+u)}{6} \tag{14}$$

Once Pcrispis calculated, the consistency index (CI) and the consistency ratio (CR) is computed as:

$$CI = \frac{I_{\max} - n}{n - 1}$$
(15)
$$CR = \frac{CI}{RI}$$
(16)

Where,

 I_{max} : the maximum eigenvalue of the given comparison matrix, n: number of criteria in the given matrix,

RI: the random index and its value can opt from Table 2.

Table 2. Random consistency index (RI) concerning matrix size

Size of the matrix	1	2	3	4	5	6	7	8	9	10
Random consistency index (RI)	0	0	0.58	0.9	1.12	1.24	1.32	1.41	1.45	1.49

If the estimated value of CR is less than 0.1, expert pair-wise responses are assumed to be consistent. Otherwise, current responses are discarded, and new responses are gathered.

4. Results and Applications of Fuzzy AHP

To address the research questions raised in Section 1, we have organized the findings of this study into the following sections:

4.1 Most cited software security risks in the SDLC phases in the domain of GSD

We previously published [2] an in-depth analysis of software security risks in the SDLC phases in the domain of Secure Software Engineering (SSE). In this paper, we employed the coding system of Strauss' [78] ground theory (GT) technique to identify, classify, and organize the identified critical security risks (CSRs) in our research. Although we have already collected the data through SLR, we used the four main phases of the GT coding scheme to map the CSRs into four major categories (i.e. "code," "categories", "sub-categories," and theory/theoretical model").

Figure 6: Theoretical model of the critical software security risks of SDLC in GSD

All three authors of this study are on the mapping team. The third author checks to make sure the mapping process is going well. First, we allocated a unique code/label to each CSR we studied. The second phase involved categorizing the examined CSRs into six broad phases/groups, "Requirement Engineering", "Designing", "Coding", "Testing", "Deployment", and "Maintenance". In the third step, the CSRs were mapped into these phases. In the fourth step, we engineered a theoretical model depicted in Figure 6.

The primary goal of this categorization is to construct a hierarchical framework for executing the FAHP. Furthermore, this categorization will help academic researchers and practitioners to identify the most important software security risk in the SDLC in the context of GSD. We identified 45 CSRs, which were mapped in each phase of the SDLC, as stated in Table 3.

SDLC Phases	Code / Label	Critical Security Risks (CSRs)						
	CSR1	Lack of security requirements, review, assessment, analysis, verification, validation						
	CSR2	Security requirements are often neglected or considered a non-functional requirement						
	CSR3	Lack of secure requirements identification and documentation						
Requirement Engineering	CSR4	Lack of experience, knowledge, guidance, and security training during security requirement documentation						
Engineering	CSR5	Improper plan for secure requirement identification, inception, authorization, and privacy						
	CSR6	Lack of security requirements elicitation activity						
	CSR7	Lack of developing threat modeling						
	CSR8	Lack of security requirements prioritization, management, and categorization						
	CSR9	Improper secure design documentation and specification review						
	CSR10	Lack of developing threat modeling during the design phase						
	CSR11	Lack of access control and traceability						
	CSR12	Improper security design review and its verification						
	CSR13	Lack of attention to following security design principles						
Designing	CSR14	Lack of developing data flow diagrams and design requirements						
	CSR15	Lack of building and maintaining abuse case models and attack patterns						
	CSR16	Lack of security design awareness, guidance, and training						
	CSR17	Lack of implementation of security design decisions: (Cryptographic protocols, standards, services, frameworks, abuse case models, and attack patterns)						
	CSR18	Tampering: is the unauthorized modification of data						
	CSR19	SQL Injection, Cross Site Scripting, cross-site request forgery						
	CSR20	Denial of Services: is the process of making a system or application unavailable						
Coding	CSR21	Repudiation: is the ability of users (legitimate or otherwise) to deny that they performed specific actions or transactions						
	CSR22	Information Disclosure: is the unwanted exposure of private data						
	CSR23	Elevation of privilege: occurs when a user with limited privileges assumes the identity of a privileged user						
	CSR24	Spoofing: An attempt to gain access to a system by using a fake identity						
	CSR25	Password Conjecture: Lack of password complexity enforcement						
	CSR26	Lack of Penetration Security Testing Analysis						
Testing	CSR27	Lack of Static and Dynamic Security Testing Analysis						
	CSR28	Lack of final and manual security review						

Table 3: list of identified critical security risks of SDLC in GSD

	CSR29	Lack of Fuzz and Unit Testing Analysis						
	CSR30	Brute Force Attack						
	CSR31	Lack of developing threat models: as it helps to develop test cases or test plans						
	CSR32	Lack of Functional and Non-Functional Testing						
	CSR33	Various kinds of Attacks (viruses,) malware, Trojan Virus: A type of virus that is well known for causing issues and destruction to computers is a Trojan virus						
	CSR34	Lack of default software configuration						
Devilence	CSR35	ack of output validation						
Deployment	CSR36	ack of certification in final release and archive						
	CSR37	ack of threat models updating						
	CSR38	Lack of proper methods to find out new threats in the system						
	CSR39	Lack of security trust						
Maintenance	CSR40	Improper configuration, vulnerability management, change control, and improvement of security assessment						
Maintellance	CSR41	Security activities increase the cost of the software						
	CSR42	Timing attacks and lack of log optimization						
	CSR43	Inability to run software updates or change usernames and passwords						
	CSR44	Lack of government assistance for proper rules for cybercrime						

4.2 Application of Analytic Hierarchy (AHP)

Throughout this part, we determine the relative importance of each investigated software security risk and between each category. Additionally, by completing all of the methods outlined in Section3.4.3, the most critical category of critical software security risks was established.

Step 1: Simplify a complex decision-making problem by dividing it into a hierarchical structure

Shameem et al. [39], Albayrak [79] and Akbar et al. [36] stated that decision-making problems are broken down into a series of interconnected components at this level. Figure 7 shows the problem's hierarchical structure divided into three stages. The problem's aim is mentioned in the first stage of this hierarchical structure; however, the components and sub-factors are situated in stages 2 and3, respectively. The hierarchical structure of the current investigation is depicted in Figure 7.

Step 2: Make a pair-by-pair comparison

This study aims to rank the critical software security risks and their categories in terms of their importance for the successful development of secure software projects. A questionnaire was designed and sent to respondents of the initial survey to conduct the pair-wise comparison (for fuzzy-AHP analysis). Participants in the survey provided a total of 27 replies. To ensure that no data was missing, all replies were rigorously examined. We discovered that all 27 of the responses were complete. Second-survey questionnaire samples are included in Appendix-A. One potential concern with fuzzy-AHP analysis is a small sample size. However, a similar-sized dataset has been utilized in previous publications [80-83] to do the AHP analysis:

Several existing studies also consider FAHP data from a small sample size. For example, Shameem et al. [39] gathered data from 5 specialists to compare the impacting elements of distributed agile development pair-wise. Similarly, Cheng and Li [82] have collected nine responses to a pair-wise comparison of the success variables for building partnering. Furthermore, Wong and Li [80] found FAHP is an effective tool for narrowing down the options for intelligent building systems during a survey of nine industry professionals. Based on these illustrations, we may conclude that a sample size of 27 is sufficient for FAHP.

The survey data from the FAHP participants have been transformed into geometric means for comparing security risks and categories side by side. A geometric mean is an efficient method for

converting survey respondents' assessments into TFN values. The following formula has been used to calculate the geometric mean: The following formula has been used to calculate the geometric mean:

Geometric mean = $n\sqrt{a1 \times a2 \times a3 \dots an}$

a = Weight of each response

n = Number of responses

The linguistic variable against their triangular fuzzy Likert scales is given in Table 1. The triangular fuzzy conversion scale (Table 1) suggested by Bozbura et al. [84] was used to create the pair-wise comparison matrixes of the reported critical software security risks and their associated categories.

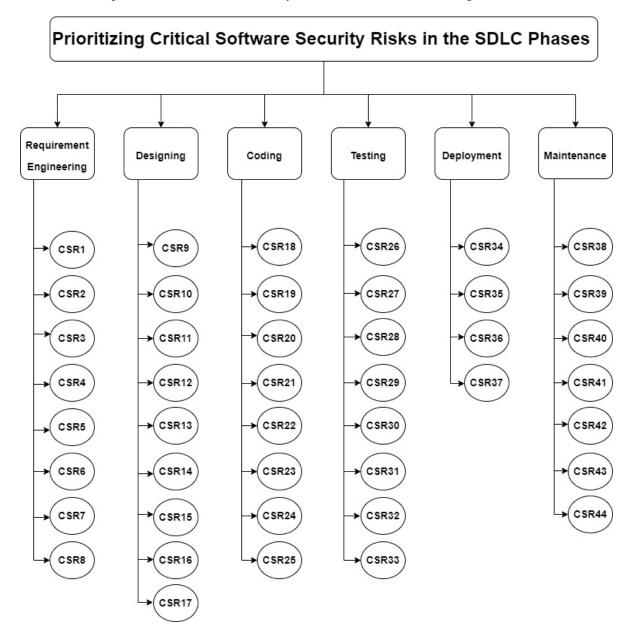

Figure 7: Proposed hierarchical structure of the critical software security risks of SDLC in GSD

Step 3: Determine the local priority weight for each security risk

We calculated the priority weight of each critical security risk (CSR) and their related phases to identify the criticality of each CSR for developing secure software applications in the context of GSD. In the first place, the synthetic extent values of four CSRs in the category "Deployment" were found. As a result, we calculated the priority weight for each CSRs in the following manner. For example, we determined local weights for the CSRs of the "Deployment" category. Table 4 shows a pair-wise analysis of CSRs in the "Deployment" category.

$$\begin{split} \sum_{i}^{n} \sum_{j}^{m} F_{gi}^{j} &= (1,1,1) + (1.5,2,2.5) + (1,1.5,2) \dots + (0.5,0.6,1) + (1,1,1) = (14.1,18.2,22.8) \\ & \left[\sum_{i}^{n} \sum_{j}^{m} F_{gi}^{j} \right]^{-1} = \left(\frac{1}{22.8}, \frac{1}{18.2}, \frac{1}{14.1} \right) = (0.04386, 0.054945, 0.070922) \\ & \sum_{j=1}^{m} F_{g1}^{j} = (1,1,1) + (1.5,2.5,3) + (1,1.5,2) + (1.5,2.0,2.5) = (5,7,8.5) \\ & \sum_{j=1}^{m} F_{g2}^{j} = (0.3,0.4,0.6) + (1,1,1) + (0.4,0.5,0.6) + (0.5,0.6,1) = (2.2,2.5,3.2) \\ & \sum_{j=1}^{m} F_{g3}^{j} = (0.5,0.6,1) + (1.5,2.2.5) + (1,1,1) + (1,1.5,2) = (4,5.1,6.5) \\ & \sum_{j=1}^{m} F_{g4}^{j} = (0.4,0.5,0.6) + (1,1.5,2) + (0.5,0.6,1) + (1,1,1) = (2.9,3.6,4.6) \end{split}$$

The following equation (4) was used to determine the synthesis values for the "Deployment" category CSRs (CSR34–CSR37):

$$CSR34 = \sum_{j}^{m} F_{g1}^{j} \otimes \left[\sum_{i}^{n} \sum_{j}^{m} F_{gi}^{j}\right]^{-1}$$

 $= (5,7,8) \otimes (0.04376, 0.054955, 0.070922) = (0.219398, 0.384515, 0.601837)$ $CSR35 = (2.3,2.5,3.2) \otimes (0.04286, 0.054845, 0.070912) = (0.095491, 0.137463, 0.226940)$ $CSR36 = (4,5.1,6) \otimes (0.04376, 0.054845, 0.070822) = (0.174439, 0.281220, 0.450993)$ $CSR37 = (2.9,3.6,5.6) \otimes (0.04286, 0.055945, 0.071922) = (0.127183, 0.197812, 0.325241)$

Table 4: Pair-wise analysi	is of CSRs in th	he "Deployment"	category

Critical Software Security Risks	CSR34	CSR35	CSR36	CSR37
CSR34	(1,1,1)	(1.5, 1.5, 1)	(1, 1.5, 3)	(1.5, 2, 0.5)

CSR37	1.5	1.5	0.7	2.5	0.41892					

 Table 6: Fuzzy Crisp Matrix (FCM) critical software security risks in the deployment phase

Equation 6 was used to compute the degree of possibility, and equation 8 was used to get the minimal degree of possibility (priority weights) for each pair-wise comparison. Table 5 shows the estimated weights, which are W'= W (1, 0.0303, 0.6972, 0.3661). The statistical significance of the data was determined by normalizing it to W = (0.085234, 0.098666, 0.085853, 0.088267, 0.073985, 0.083276).

Step 4: Consistency Check

We conducted the consistency check using Table 6 and followed all the steps necessary to determine the consistency of pair-wise comparison matrixes. As shown in Table 6, the Fuzzy Crisp Matrix (FCM) was created by converting the fuzzy triangular numbers of the pair-wise comparison matrix of the "Deployment" category CSRs into crisp numbers. To find the greatest Eigen vector (max), we added the sums of the columns of the FCM matrix together. We then divided each value by the total of its appropriate column to find the greatest Eigen vector (max) (Table 6). Finally, In Table 7, we take the average of each row and divide it by the total number of CSRs to assess their priority weight.

Table 7: Normalized matrix of CSRs in the deployment phase

	CSR34	CSR35	CSR36	CSR37
CSR34	0.3703	0.3563	0.4065	0.3835
CSR35	0.1853	0.1438	0.1343	0.1354
CSR36	0.2593	0.2848	0.2714	0.2876
CSR37	0.1855	0.2154	0.1889	0.1932

$$\lambda_{\max} = \Sigma \left(\left[\Sigma C j \right] \times \{W\} \right)$$

(17)

 ΣCj = present the sum of Matrix [C] columns (Table 7),

W= present the weight (Table 7), therefore

 $\lambda_{\text{max}} = 2.7*0.3835 + 7.0*0.1354 + 3.7*0.2876 + 5.2*0.1932 = 4.0520$

The λ_{max} of FCM matrix is 4.0520 and the matrix size is 4×4, thus according to the RI value given in Table-2 is 0.9.

Furthermore, we used the Equation 15 and Equation 16, CR is determined as follows:

$$CI = \frac{\lambda_{max} - n}{n - 1} = \frac{4.0520 - 4}{4 - 1} = \frac{0.0520}{3} = 0.0173$$
(15)
$$CR = \frac{CI}{RI} = \frac{0.0173}{0.9} = 0.0192$$
(16)

A consistent pair-wise comparison of the "Deployment" category was found to have a calculated value of CR of 0.0192< 0.10, which indicates that the category is consistent. Similarly, the consistency ratio for all the categories is evaluated, and the results, together with a pair-wise comparison of "Requirement Engineering", "Designing", "Coding", "Testing", and "Maintenance", are reported in Tables 8, 9, 10 and 11.

	CSR1	CSR2	CSR3	CSR4	CSR5	CSR6	CSR7	CSR8	Priority Weight

Step-5: Determine the relative importance of critical software security risks on a local and global weight

Table 14 shows the local and global weights for each critical software security risk (CSR) and its SDLC phase. When a CSR is given a local weight, it indicates its importance to other similar CSRs. On the other hand, the global weight reveals which of the 44CSRs has the highest priority. The pair-wise comparison was used to generate each CSR and category (step4).

For instance, Table 14 indicates that CSR5, "Improper plan for secure requirement identification, inception, authorization, and privacy", has the highest local weight (LW) in the Requirement Engineering category (0.106190), indicating that CSR5 is the highest ranked (prioritized) component in the Requirement Engineering category.

However, each CSR's global weight was computed by multiplying its local weight by the weight of its category. For example, the global weight (GW) of CSR1 = weight of its category (Requirement Engineering) multiply with it local weight = $0.085234 \times 0.099521 = 0.0084826$ as depicted in Table 14. Similarly, we estimated each reported CSR's global weight (GW) (see Table 14).

The results in Table 14 indicate that CSR37 (Lack of threat models updating, GW=0.0309938) is the highest-ranking critical software security risk in the SDLC process implementation in the GSD context.

Step 6: Prioritizing of CSRs

The final stage of the AHP process prioritizes the critical software security risks facing software development organizations. The application of this prioritizing is that software development organizations will focus on these priority base CSRs during the SDLC phases to develop a secure software application/product. This prioritization of CSRs is depicted in Table 15. The global weights are used to determine the final rankings of CSRs and calculate their relative importance.

However, the absolute rankings in Table 15 show that CSR37 (Lack of threat models updating, GW=0.0309938) is the most important CSR. This indicates that the secure software development experts have acknowledged the need for effective security management to help software development organizations effectively perform the GSD activities. We further noted (see Table 15) that CSR35 (Lack

of output validation), CSR36 (Lack of certification in the final release and archive), CSR24 (Spoofing: An attempt to gain access to a system by using a fake identity), are the second, third and fourth highest-ranking CSRs in the SDLC process in the GSD context.

Code / Label	CSRs in the SDLC phases	Priority order / global rank
CSR37	Lack of threat models updating	1
CSR35	Lack of output validation	2
CSR36	Lack of certification in final release and archive	3
CSR24	Spoofing: An attempt to gain access to a system by using a fake identity	4
CSR13	Lack of attention to follow security design principles	5
CSR18	Tampering: is the unauthorized modification of data	6
CSR22	Information Disclosure: is the unwanted exposure of private data	7
CSR16	Lack of security design awareness, guidance, and training	8
CSR10	Lack of developing threat modeling during the design phase	9
	Improper plan for secure requirement identification, inception, authentication,	
CSR5	authorization, and privacy	10
CSR9	Improper secure design documentation and specification review	11
CSR38	Lack of proper methods to find out new threats in the system	12
CSR34	Lack of default software configuration	13
CSR25	Password Conjecture: Lack of password complexity enforcement	14
CSR1	Lack of security requirements, review, assessment, analysis, verification, validation	15
CSR19	SQL Injection, Cross Site Scripting, cross-site request forgery	16
CSR8	Lack of security requirements prioritization, management, and categorization	17
CSR15	Lack of building and maintaining abuse case models and attack patterns	18
CSR41	Security activities increase the cost of the software	19
CSR20	Denial of Services: is the process of making a system or application unavailable	20
CSR2	Security requirements are often neglected or considered a non-functional requirement	21
CSR11	Lack of access control and traceability	22
CSR4	Lack of experience, knowledge, guidance, and security training during security requirement documentation	23
CSR21	Repudiation: is the ability of users (legitimate or otherwise) to deny that they performed specific actions or transactions	24
CSR3	Lack of secure requirements identification and documentation	25
CSR23	Elevation of privilege: occurs when a user with limited privileges assumes the identity of a privileged user	26
CSR17	Lack of implementation of security design decisions: (Cryptographic protocols, standards, services, frameworks, abuse case models, and attack patterns)	27
CSR43	Inability to run software updates or change usernames and passwords	28
CSR7	Lack of developing threat modeling	29
CSR12	Improper security design review and its verification	30
CSR14	Lack of developing data flow diagrams and design requirements	31
CSR42	Timing attacks and lack of log optimization	32
CSR40	Improper configuration, vulnerability management, change control, and improvement of security assessment	33
	Lack of government assistance for proper rules for cybercrime	34
CSR44		
CSR44 CSR26		
CSR26	Lack of Penetration Security Testing Analysis	35

 Table 15: List of CSRs and their priority order/global rank

CSR31	Lack of developing threat models: as it helps to build test cases or test plans	38
CSR29	Lack of Fuzz and Unit Testing Analysis	39
CSR6	Lack of security requirements elicitation activity	40
CSR39	Lack of security trust	41
CSR32	Lack of Functional and Non-Functional Testing	42
CSR28	Lack of final and manual security review	43

5. Results Evaluation and Analysis

The fuzzy analytical hierarchy approach (FAHP) is used in this paper to prioritize the critical software security risks (CSRs) in the SDLC phases in the global software development (GSD) domain. As stated in Section1, we have generated three research questions to accomplish the study's goal. The results of the evaluation and the analysis are briefly shown in the following sections:

5.1 RQ1: What are the most cited software security risks in the SDLC phases in the domain of GSD?

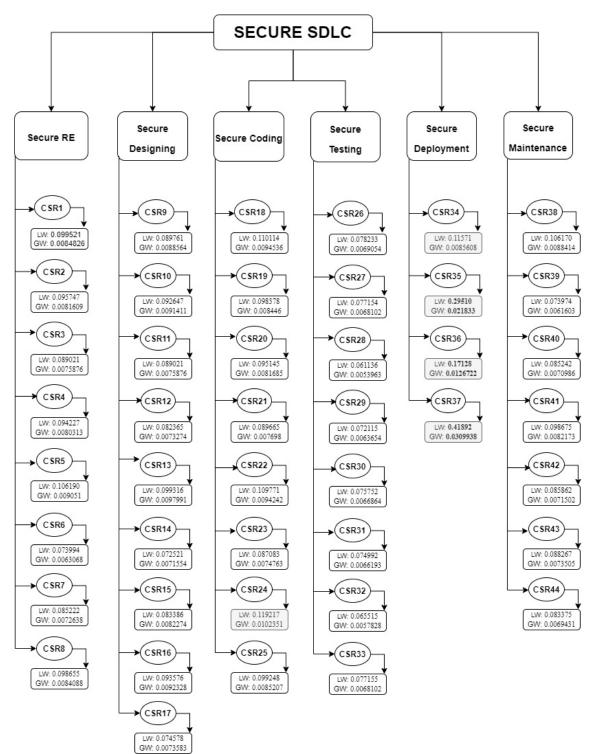

This study found 44 CSRs (see Table 15) that are essential for the SDLC process in GSD to be carried out successfully. It is based on our prior systematic literature review analysis that identified 145 software security risks [2]. Section 4.1 and Figure 6 describe the mapping approach we used to group the researched CSRs into six essential categories based on the framework developed by Shameem et al. [39]. The primary objective of security risks categorization is to establish a hierarchy process that will aid in applying the fuzzy AHP. It is also important for practitioners and academic researchers to consider the CSRs for SDLC phases implementation and future study, respectively, by using the mapping technique.

The most cited/critical software security risk is CSR37 "Lack of threat models updating", CSR35 "Lack of output validation", CSR36 "Lack of certification in final release and archive", CSR24 "Spoofing: An attempt to gain access to a system by using a fake identity" in the SDLC process in the GSD context.

5.2 RQ2: What is the best way to prioritize the significant software security risks?

The fuzzy AHP approach prioritized the examined CSRs and their categories. This was accomplished using pair-wise comparisons between the security risks and the relevant categories. The pair-wise comparison is important in determining the importance of the CSRs in the SDLC process in the context of GSD. Every CSR and its category were ranked following the priorities set. The fuzzy AHP technique enables a thorough comprehension of multi-criteria decision-making situations that incorporate the significance of SDLC process security improvement and their associated categories.

It is clear from Table 15 that CSR37, "Lack of threat models updating", is the most important CSR in the SDLC phases. For this reason, secure SDLC experts believe the software development organization should have qualified and skilled team members. On the other hand, the members of secure software development organizations must be capable of efficient communication and coordination [85, 86].

5.3 **RQ3: What would be the decision-making framework for the critical software security risks?**

Figure 8: Decision-Making Framework

Finally, taking into consideration the framework proposed by Shameem et al. [39], we develop a taxonomy by classifying the prioritized CSRs into six main categories (Secure Requirement Engineering (RE), Secure Designing, Secure Coding, Secure Testing and Review, Secure Deployment, and Secure Maintenance) in Figure 8. Each CSR is given a global and local weight in the taxonomy based on its importance. There are two types of weights: local and global. The local weight shows how a CSR affects its category, and the global weight affects the whole SDLC process. As a result, the taxonomy (Figure 8) aids in specifying the influence of a single CSR in a specific category and across the entire SDLC process.

Figure 8 shows that the most CSRs are: CSR37 "Lack of threat models updating (LW = 0.41892 and GW = 0.0309938)", CSR35 "Lack of output validation (LW = 0.29510 and GW = 0.021833)", CSR36 "Lack of certification in final release and archive (LW = 0.17128 And GW = 0.0126722)", CSR24 "Spoofing: An attempt to gain access to a system by using a fake identity (LW = 0.119217 and GW = 0.0102351)" in the SDLC process in the GSD context.

Threat modeling is a systematic method for identifying threats that may compromise security, and it is considered a well-known accepted practice by the software testing industry [87]. In CLASP, threat modeling and risk analysis are performed during the requirement and design phase. The design and implementation phase suggests secure design guidelines and coding standards [88]. Microsoft uses STRIDE to model threats to their systems; threats are defined by looking into the possibilities of spoofing identity, tampering with data, repudiation, information leakage, denial of services, and elevation in the given situation [89]. Incorrect input/output validation refers to the lack of or inaccurate validation of input/output provided by a user via the application's user interface. Injection attacks take advantage of the lack of input/output validation controls to allow malicious inputs to be passed in, which can be used to obtain elevated rights, alter data, or crash a system [90]. Code injection attacks can breach data security, cause a loss of services, and harm thousands of users' systems [91]. During the secure deployment phase, final security reviews and audits are performed [11, 36]. At this phase, customer satisfaction is also very important.

Table 14 shows that "Designing" (W = 0.098666) has been declared the most important category of the CSRs evaluated by software development industry experts. Software development experts should pay close attention to the CSRs of the designing category. Moreover, the "Testing" category (W = 0.088267), followed by "Coding" (W = 0.085853), are the second and third most important categories, respectively. Table 14 indicate that category (Designing, category weight = 0.098666) is the highest-ranking category based on software security in the SDLC process implementation. The design phase is one of the most creative stages of the SDLC, which is one of the reasons it is important from the viewpoint of security [4, 92]. 50 % of software defects are identified and detected during the design stage of the SDLC [4, 92, 93]. Design-level flaws are software systems' most common security risks [4]. Designation-level flaws are software systems' most common security risks [4]. Designation-level flaws are software that functions properly even under malicious attacks [94]. This requires addressing the security challenges throughout the SDLC, especially in the early stages of the design phase [95]. This reduces the risk of overlooking critical security requirements or introducing security flaws throughout the implementation process. To complete this phase appropriately and securely, the software developer must consider security best practices during design.

6. Study Limitations

It is necessary to elaborate potential risks of this study before using the findings in industry or for other research purposes. For example, the sample size of FAHP survey responses is n = 27, which may not be strong enough to support the validity of the reported CSRs when evaluating their explanation. Compared to the previous survey, the FAHP survey had a smaller sample size (27 replies), threatening the

generalizability of our results. The FAHP method, on the other hand, has been viewed as a more subjective approach that allows for smaller sample size [65-68, 96].

Construct validity measures how well an assessment scale is used to examine the supplied CSRs' work. A questionnaire survey was conducted with real-world software development practitioners to determine the significance of the researched elements concerning the SDLC process in GSD. Following the findings, the parameters identified could favour the SDLC process in the GSD context.

Internal validity is the evaluation of the results and analyses presented in the study. The results of pilot research we conducted with secure software development specialists show that the study has an adequate level of internal validity.

External validity refers to the ability of a study's results to be generalized. The survey participants in this study came from various continents and nations, yet we are convinced that the data sample was sufficiently representative and generalizable.

7. Study Implications

It is hoped that the findings of this study will have both practical and research consequences because they give a prioritized set of SDLC critical software security risks, which will serve as a knowledge base for industry practitioners and academic scholars in the field of GSD. The classification of the researched CSRs aids the researchers in determining the most important category of CSR to consider when planning their future studies. Furthermore, the study gives a prioritization-based taxonomy of the aspects that contributed to the success of secure software development applications.

Prioritization-based taxonomy helps GSD practitioners consider the most important CSRs related to their specific categories based on the most important local rankings. Using the taxonomy, the practitioners (software development organizations) may see the global rankings of each CSR, making it easier for them to identify the CSR while implementing secure SDLC-related requirements modifications. In summary, this study presents a complete analysis of the GSD and secure SDLC critical software security risks and their priority order, which has not been done in this field. We believe that the study's findings will aid software development industry practitioners in building effective plans for successfully executing secure SDLC operations in the context of GSD.

8. Conclusion and Future Directions

An increase in GSD projects prompted us to study and prioritize the aspects that could positively impact SDLC. The CSRs that have been documented emphasize the critical areas that must be addressed with urgency for the secure SDLC process to be successfully implemented in the GSD. One hundred forty-five software security risks were found due to the systematic literature review approach that we have used [2]. The security risks observed were then divided into six distinct software development process improvement areas. Furthermore, a questionnaire survey has been used to determine what software development industry professionals think about the security risks of SDLC phases in GSD. According to the empirical data analysis, more than 70% of survey participants agreed that the enlisted security risks are important to consider when developing secure software in the GSD context.

As a result of the FAHP approach, the "Designing" category is by far the most significant identified CSRs. In addition, the FAHP results show that "Lack of threat models updating", "Lack of output validation", and "Lack of certification in final release and archive" are the three most important CSRs in the designing category.

Software development organizations in the GSD domain could benefit from a taxonomy of CSRs that can amend and evaluate their SDLC strategies based on the categorization, weighting, and prioritizing of CSRs. The taxonomy presented here is based on a hierarchical and multidimensional model that incorporates the significance of SDLC activities in the GSD environment in the six core categories.

We believe that the findings, analysis, and conclusions of this study will be useful in addressing the issues related to the improvement of the SDLC process, which is critical to the success and development of GSD businesses.

With the increasing number of software security threats, regularly upgrade software security processes and practices. This study project can be improved in a variety of ways. The following are some of the open study directions that researchers can look into near future:

- We intend to develop a security tool from a Security Assurance Model (SAM) of Software Development [16, 97] for global software development (GSD) vendor organizations. This model will assist GSD vendors in determining their readiness for secure software development. We will develop the model using the results of this study, SLR, industrial survey, case study, supervisor inputs, and lessons learned from the existing studies [5, 8, 12, 98-100]. The model will generate several assessment reports, including a list of security risks/threats and practices that GSD vendor organizations will use in each phase of the SDLC.
- Collaboration with software development organizations is required to improve the outcomes of SAM of Software Development. Depending on the facilities and methods used, it might be adapted to meet the needs of various organizations.
- The SAM of Software Development might include characteristics relating to specific technologies like the Internet of Things (IoT), blockchain, and cloud computing.
- The SAM of Software Development might be made available as an online repository (tool) updated regularly with new academic and industry practices. The SAM of Software Development will become a reliable resource for scholars and practitioners.

Acknowledgment

We thank the Software Engineering Research Group at the University of Malakand, the questionnaire survey, and FAHP Survey participants for their critiques and contributions to this project (SERG UOM).

Section- A1 (Responde	ent Information)	Section- A1 (Respondent Information)						
Full Name (optional)		Position						
Secure Software Development working experience (Years)?								
Email Address								
Address of your current organization including the country name								
Total academic/industrial experience in years								
Have you ever participated in Secure Software Development process?	Yes	No						
Section- A2 (Organizat	Section- A2 (Organization Detail)							

Appendix-A: (Sample of Fuzzy AHP Survey Questionnaire)

Current organization name (Optional)						
What is the primary business of your	Global/offsho Development		Collocated/single site development			
organization? (You may tick more than one)	Research		Other			
Size of your current organization	Small		Medium			
organization	Large		Not sure			
Please specify your organization type	National		Multinational			
organization type	Not sure		Other			
Does your organization adopt Secure Software Developmentstandards or models?(Please specify)						
For how long your organization is using the Secure Software Development standard/model? (Years)	ing					
Section B- Pair-wise C	omparison of	the Identified Critical Software	e Security Risks (CSRs) and Categories			
Categories (SDLC Phases)	Code / Label	Critical S	Security Risks (CSRs)			
	CSR1	"Lack of security requirement validation"	s, review, assessment, analysis, verification,			
	CSR2	"Security requirements are often neglected or considered as a non- functional requirement"				
	CSR3	"Lack of secure requirements i	dentification and documentation"			
Requirement Engineering	CSR4	"Lack of experience, knowledge, guidance, and security training during security requirement documentation"				
	CSR5	"Improper plan for secure requirement identification, inception, authentication, authorization and privacy"				
	CSR6	"Lack of security requirements	elicitation activity"			
	CSR7	"Lack of developing threat mo	deling"			
	CSR8	"Lack of security requirements	prioritization, management and			

		categorization"
	CSR9	"Improper secure design documentation and specification review"
	CSR10	"Lack of developing threat modeling during the design phase"
	CSR11	"Lack of access control and traceability"
	CSR12	"Improper security design review and its verification"
	CSR13	"Lack of attention to follow security design principles"
Designing	CSR14	"Lack of developing data flow diagrams and design requirements"
	CSR15	"Lack of building and maintaining abuse case models and attack patterns"
	CSR16	"Lack of security design awareness, guidance, and training"
	CSR17	"Lack of implementation of security design decisions: (Cryptographic protocols, standards, services, frameworks, abuse case models and attack patterns)"
	CSR18	"Tampering: is the unauthorized modification of data"
	CSR19	"SQL Injection, Cross Site Scripting, cross-site request forgery"
	CSR20	"Denial of Services: is the process of making a system or application unavailable"
Coding	CSR21	"Repudiation: is the ability of users (legitimate or otherwise) to deny that they performed specific actions or transactions"
U	CSR22	"Information Disclosure: is the unwanted exposure of private data"
	CSR23	"Elevation of privilege: occurs when a user with limited privileges assumes the identity of a privileged user"
	CSR24	"Spoofing: An attempt to gain access to a system by using a fake identity"
	CSR25	"Password Conjecture: Lack of password complexity enforcement"
	CSR26	"Lack of Penetration Security Testing Analysis"
	CSR27	"Lack of Static and Dynamic Security Testing Analysis"
	CSR28	"Lack of final and manual security review"
Testing	CSR29	"Lack of Fuzz and Unit Testing Analysis"
	CSR30	"Brute Force Attack"
	CSR31	"Lack of developing threat models: as it helps to develop test cases or test plans"
	CSR32	"Lack of Functional and Non Functional Testing"

	CSR33	"Various kinds of Attacks (viruses,) malware, Trojan Virus: A type of virus that is well known for causing issues and destruction to computers is a Trojan virus"
	CSR34	"Lack of default software configuration"
	CSR35	"Lack of output validation"
Deployment	CSR36	"Lack of certification in final release and archive"
	CSR37	"Lack of threat models updating"
	CSR38	"Lack of proper methods to find out new threats in the system"
	CSR39	"Lack of security trust"
	CSR40	"Improper configuration, vulnerability management, change control and improvement of security assessment"
Maintenance	CSR41	"Security activities increase the cost of the software"
	CSR42	"Timing attacks and lack of log optimization"
	CSR43	"Inability to run software updates or change usernames and passwords"
	CSR44	"Lack of government assistance for proper rules for cybercrime"

Perform the pair-wise comparison of the CSRs and the given categories by putting the checkmark (\checkmark). For example, if a CSR on the left side of Table 1 is more significant than the right side, then put the checkmark on the left side of the scale just equal (JE) based on your preference. Similarly, if a category on the right side of Table 1 is more important than the matching category at the left, then put the checkmark on the right side of the scale just equal (JE).

Table 1 refersto a questionnaire hierarchal structure to determine the weight priorities of the CSRs and their respective categories by putting the checkmark on the pair-wise comparison matrices. For example, how important is CSR1 as compared to CSR2 when we execute SDLCimprovement activities in global software development domain.

Description	Significance intensity
Just equal (JE)	(1,1,1)
Equally important (EI)	(1/2,1,3/2)
Weakly important (WI)	(1,3/2,2)
Strong more important (SMI)	(3/2,2,5/2)
Very strong more important (VSMI)	(2,5/2,3)

To perform the pair-wise comparison of the CSRS and the given categories by putting the checkmark (\checkmark). For example, if a CSR on the left side of Table 1 is more significant than the right side, then put the checkmark on the left side of the scale i.e. 1 (Equal) based on your preference. Similarly, if a category on the right side of Table1 is more important than the matching category at the left, then put the checkmark on the right side of the scale 1 (Equal).

Table 1 refersto a questionnaire hierarchal structure to determine the weight priorities of the SDLCcritical software security risks and their respective categories by putting the checkmark on the pair-wise comparison matrices. For example, how important is CSR1 as compared to CSR2 when we execute SDLC process activities in GSD?
